PROJECT DEVELOPMENT – PHASE 2

Requirement Analysis Phase

Project Title: Auto Ticket Classification using FLOW DESIGNER

Phase: 2 – Requirement Analysis

1. Introduction

Requirement Analysis is the second phase of the project development process. In this phase, the requirements needed to develop the Auto Ticket Classification system are identified and documented. The analysis focuses on what the system should do, what inputs it requires, how the Flow Designer should process tickets, and what outputs are expected.

2. Problem Analysis

Support teams may receive many tickets with different types of issues. Manual classification can consume time and may result in inconsistent categorization or incorrect routing. The proposed system therefore requires an automated workflow that can examine ticket information and classify the ticket according to predefined rules.

3. Functional Requirements

Requirement	Description
Ticket Trigger	The flow should start when a relevant ticket is created or updated.
Data Retrieval	The flow should access the required ticket fields and information.
Condition Checking	The flow should evaluate predefined conditions or rules.
Classification	The system should identify the appropriate ticket category.
Assignment/Routing	The classified ticket can be routed or assigned to the relevant group or process.
Record Update	The flow should update required ticket fields when applicable.
Notification	The system may provide an appropriate notification or update after processing.

4. Non-Functional Requirements

- Usability – The workflow should be simple to understand and maintain.
- Reliability – The flow should process tickets consistently when the defined conditions are satisfied.
- Performance – Ticket classification should be completed without unnecessary processing steps.
- Maintainability – Rules and workflow actions should be easy to modify when requirements change.
- Security – Access to ticket information and workflow configuration should follow the platform's access controls.

5. Input Requirements

- Ticket number or unique ticket identifier.
- Ticket description or relevant ticket details.
- Category-related fields or other fields required for classification.
- Assignment/group information when routing is required.
- Status and other relevant ticket attributes.

6. Processing Requirements

The Flow Designer should receive the ticket event, read the required information, evaluate the configured conditions, determine the classification, and perform the required action such as updating fields or routing the ticket. The workflow should also handle cases where a ticket does not match a predefined condition.

7. Output Requirements

Output	Expected Result
Ticket Category	The ticket is classified into the appropriate category.
Assignment	The ticket is routed or assigned when required.
Updated Record	Relevant ticket information is updated by the flow.
Processing Status	The ticket remains available for further support processing.

8. Technology / Platform Requirements

The project requires access to the platform that provides **Flow Designer**, along with the necessary application/module, tables or records, user access, and permissions required to create, test, and execute the flow.

9. Requirement Summary

The requirement analysis establishes that the project needs a trigger-based workflow, ticket information, classification rules, conditional logic, and suitable actions. These requirements form the basis for designing the system workflow in the next phase.

10. Conclusion

The Requirement Analysis phase defines the functional and non-functional requirements of the Auto Ticket Classification using FLOW DESIGNER project. A clear understanding of inputs, processing, outputs, and platform requirements will help in developing an effective and testable workflow.
